Configuring Port-Based and Client-Based Access Control (802.1X)

Overview

Why Use Port-Based or Client-Based Access Control?

Local Area Networks are often deployed in a way that allows unauthorized clients to attach to network devices, or allows unauthorized users to get access to unattended clients on a network. Also, the use of DHCP services and zero configuration make access to networking services easily available. This exposes the network to unauthorized use and malicious attacks. While access to the network should be made easy, uncontrolled and unauthorized access is usually not desirable. 802.1X simplifies security management by providing access control along with the ability to control user profiles from up to three RADIUS servers while allowing a given user to use the same entering valid user credentials for access from multiple points within the network.

General Features

802.1X on the switches covered in this guide includes the following:

- Support for eight users per port
- Switch operation as both an authenticator (for supplicants having a point-to-point connection to the switch) and as a supplicant for point-to-point connections to other 802.1X-aware switches.
  - Authentication of 802.1X access using a RADIUS server and either the EAP or CHAP protocol.
  - Provision for enabling clients that do not have 802.1 supplicant software to use the switch as a path for downloading the software and initiating the authentication process (802.1X Open VLAN mode).
  - Client-Based access control option with support for up to 8 authenticated clients per-port.

Configuring Port-Based and Client-Based Access Control (802.1X)

Overview

- Port-Based access control option allowing authentication by a single client to open the port. This option does not force a client limit and, on a port opened by an authenticated client, allows unlimited client access without requiring further authentication.
- Supplicant implementation using CHAP authentication and independent user credentials on each port.
- Local authentication of 802.1X clients using the switch's local username and password (as an alternative to RADIUS authentication).
- On-demand change of a port's configured VLAN membership status to support the current client session.
- Session accounting with a RADIUS server, including the accounting update interval.
- Use of Show commands to display session counters.
- Support for concurrent use of 802.1X and either Web authentication or MAC authentication on the same port.
- For unauthenticated clients that do not have the necessary 802.1X supplicant software (or for other reasons related to unauthenticated clients), there is the option to configure an Unauthorized-Client VLAN. This mode allows you to assign unauthenticated clients to an isolated VLAN through which you can provide the necessary supplicant software and/or other services you want to extend to these clients.

User Authentication Methods

The switch offers two methods for using 802.1X access control. Generally, the “Port Based” method supports one 802.1X-authenticated client on a port, which opens the port to an unlimited number of clients. The “Client-Based” method supports up to 8 802.1X-authenticated clients on a port. In both cases, there are operating details to be aware of that can influence your choice of methods.

802.1X Client-Based Access Control

802.1X operation with access control on a per-client basis provides client-level security that allows LAN access to individual 802.1X clients (up to 8 per port), where each client gains access to the LAN by entering valid user credentials. This operation improves security by opening a given port only to individually authenticated clients, while simultaneously blocking access to the same port for clients that cannot be authenticated. All sessions must use the same untagged VLAN. Also, an authenticated client can use any tagged VLAN memberships statically configured on the port, provided the client is configured to use the tagged VLAN memberships available on the port. (Note that
the session total includes any sessions begun by the Web Authentication or
MAC Authentication features covered in chapter 3.) For more information,
refer to “Option For Authenticator Ports: Configure Port-Security To Allow
Only 802.1X-Authenticated Devices” on page 9-44.

802.1X Port-Based Access Control

802.1X port-based access control provides port-level security that allows LAN
access only on ports where a single 802.1X-capable client (supplicant) has
entered authorized RADIUS user credentials. For reasons outlined below, this
option is recommended for applications where only one client at a time can
connect to the port. Using this option, the port processes all traffic as if it
comes from the same client. Thus, in a topology where multiple clients can
connect to the same port at the same time:

■ If the first client authenticates and opens the port, and then another client
  authenticates, the port responds as if the original client has initiated a
  reauthentication. With multiple clients authenticating on the port, the
  RADIUS configuration response to the latest client authentication
  replaces any other configuration from an earlier client authentication. If
  all clients use the same configuration this should not be a problem. But if
  the RADIUS server responds with different configurations for different
  clients, then the last client authenticated will effectively lock out any
  previously authenticated client. When any client to authenticate closes
  its session, the port will also close and remain so until another client
  successfully authenticates.

■ The most recent client authentication determines the untagged VLAN
  membership for the port. Also, any client able to use the port can access
  any tagged VLAN memberships statically configured on the port, provided
  the client is configured to use the available, tagged VLAN memberships.

■ If the first client authenticates and opens the port, and then one or more
  other clients connect without trying to authenticate, then the port config-
  uration as determined by the original RADIUS response remains
  unchanged and all such clients will have the same access as the authenti-
  cated client. When the authenticated client closes the session, the port
  will also be closed to any other, unauthenticated clients that may have
  also been using the port.

This operation unblocks the port while an authenticated client session is in
progress. In topologies where simultaneous, multiple client access is possible
this can allow unauthorized and unauthenticated access by another client
while an authenticated client is using the port. If you want to allow only
authenticated clients on the port, then client-based access control (page 9-4)
should be used instead of port-based access control. Using the client-based
method enables you to specify up to 8 authenticated clients.
Overview

**Note**  
Port-Based 802.1X can operate concurrently with Web-Authentication or MAC-Authentication on the same port. However, this is not a commonly used application and is not generally recommended. For more information, refer to “Operating Notes” on page 9-62.

**Alternative To Using a RADIUS Server**

Note that you can also configure 802.1X for authentication through the switch's local username and password instead of a RADIUS server, but doing so increases the administrative burden, decentralizes user credential administration, and reduces security by limiting authentication to one Operator password set for all users.

**Accounting**

The switches covered in this guide also provide RADIUS Network accounting for 802.1X access. Refer to chapter 5, “RADIUS-Administered CoS and Rate-Limiting”.
Terminology

802.1X-Aware: Refers to a device that is running either 802.1X authenticator software or 802.1X client software and is capable of interacting with other devices on the basis of the IEEE 802.1X standard.

Authorized-Client VLAN: Like the Unauthorized-Client VLAN, this is a conventional, static VLAN previously configured on the switch by the System Administrator. The intent in using this VLAN is to provide authenticated clients with network services that are not available on either the port’s statically configured VLAN memberships or any VLAN memberships that may be assigned during the RADIUS authentication process. While an 802.1X port is a member of this VLAN, the port is untagged. When a port loses its authenticated client connection, it drops its membership in this VLAN. Note that with multiple clients on a port, all such clients use the same untagged, port-based VLAN membership.

Authentication Server: The entity providing an authentication service to the switch when the switch is configured to operate as an authenticator. In the case of a switch running 802.1X, this is a RADIUS server (unless local authentication is used, in which case the switch performs this function using its own username and password for authenticating a supplicant).

Authenticator: In ProCurve applications, a switch that requires a supplicant to provide the proper credentials before being allowed access to the network.

Client: In this application, an end-node device such as a management station, workstation, or mobile PC linked to the switch through a point-to-point LAN link.

Client-Based Authentication: The 802.1X extension in the switches covered in this guide. In this operation, multiple clients on the same port must individually authenticate themselves.

Guest VLAN: See “Unauthorized-Client VLAN”.

EAP (Extensible Authentication Protocol): EAP enables network access that supports multiple authentication methods.
**EAPOL:** Extensible Authentication Protocol Over LAN, as defined in the 802.1X standard.

**Friendly Client:** A client that does not pose a security risk if given access to the switch and your network.

**MD5:** An algorithm for calculating a unique digital signature over a stream of bytes. It is used by CHAP to perform authentication without revealing the shared secret (password).

**PVID (Port VID):** This is the VLAN ID for the untagged VLAN to which an 802.1X port belongs.

**Port-Based Authentication:** In this operation, the first client on a port to authenticate itself unblocks the port for the duration of the client’s 802.1X-authenticated session. The switches covered in this guide use port-based authentication.

**Static VLAN:** A VLAN that has been configured as “permanent” on the switch by using the CLI `vlan < vid >` command or the Menu interface.

**Supplicant:** The entity that must provide the proper credentials to the switch before receiving access to the network. This is usually an end-user workstation, but it can be a switch, router, or another device seeking network services.

**Tagged Membership in a VLAN:** This type of VLAN membership allows a port to be a member of multiple VLANs simultaneously. If a client connected to the port has an operating system that supports 802.1Q VLAN tagging, then the client can access VLANs for which the port is a tagged member. If the client does not support VLAN tagging, then it can access only a VLAN for which the port is an untagged member. (A port can be an untagged member of only one port-based VLAN at a time.) Where a port is a tagged member of a VLAN, 802.1X Open VLAN mode does not affect the port’s access to the VLAN unless the port is statically configured as a member of a VLAN that is also configured as the Unauthorized-Client or Authorized-Client VLAN. See also “Untagged Membership in a VLAN”.

**Unauthorized-Client VLAN:** A conventional, static VLAN statically configured on the switch. It is used to provide access to a client prior to authentication, and is sometimes termed a guest VLAN. It should be set up to allow an unauthenticated client to access only the initialization services necessary to establish an authenticated connection, plus any other desirable services whose use by an unauthenticated client poses no security threat to your network. (Note that an unauthenticated client has access to all network resources that have membership in the VLAN you
designate as the Unauthorized-Client VLAN. A port configured to use a given Unauthorized-Client VLAN does not have to be statically configured as a member of that VLAN as long as at least one other port on the switch is statically configured as a tagged or untagged member of the same Unauthorized-Client VLAN. An unauthorized-client VLAN is available on a port only if there is no authenticated client already using the port.

**Untagged Membership in a VLAN:** A port can be an untagged member of only one VLAN. (In the factory-default configuration, all ports on the switch are untagged members of the default VLAN.) An untagged VLAN membership is *required* for a client that does not support 802.1q VLAN tagging. A port can simultaneously have one untagged VLAN membership and multiple tagged VLAN memberships. Depending on how you configure 802.1X Open VLAN mode for a port, a statically configured, untagged VLAN membership may become unavailable while there is a client session on the port. See also “**Tagged Membership in a VLAN**”.

General 802.1X Authenticator Operation

This operation provides security on a point-to-point link between a client and the switch, where both devices are 802.1X-aware. (If you expect desirable clients that do not have the necessary 802.1X supplicant software, you can provide a path for downloading such software by using the 802.1X Open VLAN mode—refer to “802.1X Open VLAN Mode” on page 9-28.)

Example of the Authentication Process

Suppose that you have configured a port on the switch for 802.1X authentication operation, which blocks access to the LAN through that port. If you then connect an 802.1X-aware client (supplicant) to the port and attempt to log on:

1. The switch responds with an identity request.
2. The client responds with a user name that uniquely defines this request for the client.
3. The switch responds in one of the following ways:
   - If 802.1X on the switch is configured for RADIUS authentication, the switch then forwards the request to a RADIUS server.
     i. The server responds with an access challenge which the switch forwards to the client.
     ii. The client then provides identifying credentials (such as a user certificate), which the switch forwards to the RADIUS server.
     iii. The RADIUS server then checks the credentials provided by the client.
     iv. If the client is successfully authenticated and authorized to connect to the network, then the server notifies the switch to allow access to the client. Otherwise, access is denied and the port remains blocked.
   - If 802.1X on the switch is configured for local authentication, then:
     i. The switch compares the client’s credentials to the username and password configured in the switch (Operator level).
     ii. If the client is successfully authenticated and authorized to connect to the network, then the switch allows access to the client. Otherwise, access is denied and the port remains blocked for that client.
General 802.1X Authenticator Operation

Note

The switches covered in this guide can use either 802.1X port-based authentication or 802.1X client-based authentication. For more information, refer to “802.1X Port-Based Access Control” on page 9-5.

VLAN Membership Priority

Following client authentication, an 802.1X port resumes membership in any tagged VLANs for which it is already assigned in the switch configuration. The port also becomes an untagged member of one VLAN according to the following order of options:

a. **1st Priority**: The port joins a VLAN to which it has been assigned by a RADIUS server during client authentication.

b. **2nd Priority**: If RADIUS authentication does not include assigning the port to a VLAN, then the switch assigns the port to the VLAN entered in the port’s 802.1X configuration as an Authorized-Client VLAN, if configured.

c. **3rd Priority**: If the port does not have an Authorized-Client VLAN configured, but does have a static, untagged VLAN membership in its configuration, then the switch assigns the port to this VLAN.

A port assigned to a VLAN by an Authorized-Client VLAN configuration (or a RADIUS server) will be an untagged member of the VLAN for the duration of the authenticated session. This applies even if the port is also configured in the switch as a tagged member of the same VLAN.

Note

On the switches covered in this guide, using the same port for both RADIUS-assigned clients and clients using a configured, Authorized-Client VLAN is not recommended. This is because doing so can result in authenticated clients with mutually exclusive VLAN priorities, which means that some authenticated clients can be denied access to the port. Refer to figure 9-1 on page 9-12.
Figure 9-1. Priority of VLAN Assignment for an Authenticated Client
General Operating Rules and Notes

- In the client-based mode, when there is an authenticated client on a port, the following traffic movement is allowed:
  - Multicast and broadcast traffic is allowed on the port.
  - Unicast traffic to authenticated clients on the port is allowed.
  - All traffic from authenticated clients on the port is allowed.

- When a port on the switch is configured as either an authenticator or supplicant and is connected to another device, rebooting the switch causes a re-authentication of the link.

- Using client-based 802.1X authentication, when a port on the switch is configured as an authenticator the port allows only authenticated clients up to the currently configured client limit.

  For clients that do not have the proper 802.1X supplicant software, the optional 802.1X Open VLAN mode can be used to open a path for downloading 802.1X supplicant software to a client or to provide other services for unauthenticated clients. Refer to “802.1X Open VLAN Mode” on page 9-28.

- Using port-based 802.1X authentication, when a port on the switch is configured as an authenticator, one authenticated client opens the port. Other clients that are not running an 802.1X supplicant application can have access to the switch and network through the opened port. If another client uses an 802.1X supplicant application to access the opened port, then a re-authentication occurs using the RADIUS configuration response for the latest client to authenticate. To control access by all clients, use the client-based method.

- When a switch port is configured with client-based authentication to accept multiple 802.1X (and/or Web- or MAC-Authentication) client sessions, all authenticated clients must use the same port-based, untagged VLAN membership assigned for the earliest, currently active client session. Thus, on a port where one or more authenticated client sessions are already running, all such clients will be on the same untagged VLAN. If a RADIUS server subsequently authenticates a new client, but attempts to re-assign the port to a different, untagged VLAN than the one already in use for the previously existing, authenticated client sessions, the connection for the new client will fail. For more on this topic, refer to “802.1X Open VLAN Mode” on page 9-28. (Note that if the port is statically configured with any tagged VLAN memberships, any authenticated client configured to use these tagged VLANs will have access to them.)
Configuring Port-Based and Client-Based Access Control (802.1X)
General Operating Rules and Notes

- If a port on switch “A” is configured as an 802.1X supplicant and is connected to a port on another switch, “B”, that is not 802.1X-aware, access to switch “B” will occur without 802.1X security protection.

- On a port configured for 802.1X with RADIUS authentication, if the RADIUS server specifies a VLAN for the supplicant and the port is a trunk member, the port will be blocked. If the port is later removed from the trunk, the port will allow authentication of the supplicant. Similarly, if the supplicant is authenticated and later the port becomes a trunk member, the port will be blocked. If the port is then removed from the trunk, it will allow the supplicant to re-authenticate.

- If a client already has access to a switch port when you configure the port for 802.1X authenticator operation, the port will block the client from further network access until it can be authenticated.

- A port can be configured as an authenticator or an 802.1X supplicant, or both. Some configuration instances block traffic flow or allow traffic to flow without authentication. Refer to “Configuring Switch Ports To Operate As Supplicants for 802.1X Connections to Other Switches” on page 9-45.

- To help maintain security, 802.1X and LACP cannot both be enabled on the same port. If you try to configure 802.1X on a port already configured for LACP (or the reverse) you will see a message similar to the following:
  
  **Error configuring port X: LACP and 802.1X cannot be run together.**
General Setup Procedure for 802.1X Access Control

Do These Steps Before You Configure 802.1X Operation

1. Configure a local username and password on the switch for both the Operator (login) and Manager (enable) access levels. (While this may or may not be required for your 802.1X configuration, ProCurve recommends that you use a local username and password pair at least until your other security measures are in place.)

2. Determine which ports on the switch you want to operate as authenticators and/or supplicants, and disable LACP on these ports. (See the “Note” on page 9-18.)

3. Determine whether to use client-based access control (page 9-4) or port-based access control (page 9-5).

4. Determine whether to use the optional 802.1X Open VLAN mode for clients that are not 802.1X-aware; that is, for clients that are not running 802.1X supplicant software. (This will require you to provide downloadable software that the client can use to enable an authentication session.) For more on this topic, refer to “802.1X Open VLAN Mode” on page 9-28.

5. For any port you want to operate as a supplicant, determine the user credentials. You can either use the same credentials for each port or use unique credentials for individual ports or subgroups of ports. (This can also be the same local username/password pair that you assign to the switch.)

6. Unless you are using only the switch’s local username and password for 802.1X authentication, configure at least one RADIUS server to authenticate access requests coming through the ports on the switch from external supplicants (including switch ports operating as 802.1X supplicants). You can use up to three RADIUS servers for authentication; one primary and two backups. Refer to the documentation provided with your RADIUS application.
Overview: Configuring 802.1X Authentication on the Switch

This section outlines the steps for configuring 802.1X on the switch. For detailed information on each step, refer to the following:

- “802.1X Client-Based Access Control” on page 9-4
- “802.1X Port-Based Access Control” on page 9-5
- “Configuring Switch Ports To Operate As Supplicants for 802.1X Connections to Other Switches” on page 9-45.

1. Enable 802.1X client-based or port-based authentication on the individual ports you want to serve as authenticators. On the ports you will use as authenticators, either accept the default 802.1X settings or change them, as necessary. Note that, by default, the port-control parameter is set to auto for all ports on the switch. This requires a client to support 802.1X authentication and to provide valid credentials to get network access. Refer to page 9-18.

2. If you want to provide a path for clients without 802.1X supplicant software to download the software so that they can initiate an authentication session, enable the 802.1X Open VLAN mode on the ports you want to support this feature. Refer to page 9-28.

3. Configure the 802.1X authentication type. Options include:
   - Local Operator username and password (the default). This option allows a client to use the switch’s local username and password as valid 802.1X credentials for network access.
   - EAP RADIUS: This option requires your RADIUS server application to support EAP authentication for 802.1X.
   - CHAP (MD5) RADIUS: This option requires your RADIUS server application to support CHAP (MD5) authentication.
   Refer to page 9-23.

4. If you select either eap-radius or chap-radius for step 3, use the radius host command to configure up to three RADIUS server IP address(es) on the switch. See page 9-24.

5. Enable 802.1X authentication on the switch. Refer to “1. Enable 802.1X Authentication on Selected Ports” on page 9-18.

6. Test both the authorized and unauthorized access to your system to ensure that the 802.1X authentication works properly on the ports you have configured for port-access.
If you want to implement the optional port security feature (step 7) on the switch, you should first ensure that the ports you have configured as 802.1X authenticators operate as expected.

7. If you are using Port Security on the switch, configure the switch to allow only 802.1X access on ports configured for 802.1X operation, and (if desired) the action to take if an unauthorized device attempts access through an 802.1X port. Refer to page 9-44.

8. If you want a port on the switch to operate as a supplicant on a port operating as an 802.1X authenticator on another device, then configure the supplicant operation. (Refer to “Configuring Switch Ports To Operate As Supplicants for 802.1X Connections to Other Switches” on page 9-45.)

1. Enable 802.1X Authentication on Selected Ports

This task configures the individual ports you want to operate as 802.1X authenticators for point-to-point links to 802.1X-aware clients or switches, and consists of two steps:

A. Enable the selected ports as authenticators.

B. Specify either client-based or port-based 802.1X authentication.

(Actual 802.1X operation does not commence until you perform step 5 on page 9-24 to activate 802.1X authentication on the switch.)

**Note**

If you enable 802.1X authentication on a port, the switch automatically disables LACP on that port. However, if the port is already operating in an LACP trunk, you must remove the port from the trunk before you can configure it for 802.1X authentication.

A. Enable the Selected Ports as Authenticators and Enable the (Default) Port-Based Authentication

**Syntax:**

```plaintext
[ no ] aaa port-access authenticator < port-list >
```

Enables specified ports to operate as 802.1X authenticators and enables port-based authentication. (To enable client-based authentication, execute this command first, and then execute the client-limit < port-list > version of this command described in the next section.) The `no` form of the command removes 802.1X authentication from `<port-list>`. To activate configured 802.1X operation, you must enable 802.1X authentication. Refer to “5. Enable 802.1X Authentication on the switch” on page 9-16.

B. Specify Client-Based or Return to Port-Based 802.1X Authentication

**Client-Based 802.1X Authentication.**

**Syntax:**

```plaintext
aaa port-access authenticator client-limit < port-list > < 1 - 8 >
```

Used after executing `aaa port-access authenticator < port-list >` (above) to convert authentication from port-based to client-based. Specifies client-based 802.1X authentication and the maximum number of 802.1X-authenticated client sessions allowed on each of the ports in `<port-list>`. If a port currently has no authenticated client sessions, the next authenticated client session the port accepts determines the untagged VLAN membership to which the port is assigned during the
Configuring Port-Based and Client-Based Access Control (802.1X)
Configuring Switch Ports as 802.1X Authenticators

session. If another client session begins later on the same port while an earlier session is active, the later session will be on the same untagged VLAN membership as the earlier session.

Note: Because a switch allows 802.1X authentication and Web or MAC authentication to co-exist on the same port, the sum of authenticated client sessions allowed on a given port for both 802.1X and either Web- or MAC-authentication cannot exceed 8.

Port-Based 802.1X Authentication.

no aaa port-access authenticator client-limit

Used to convert a port from client-based authentication to port-based authentication, which is the default setting for ports on which authentication is enabled. (Executing `aaa port-access authenticator <port-list>` enables 802.1X authentication on `<port-list>` and enables port-based authentication—page 9-18.) If a port currently has no authenticated client sessions, the next authenticated client session the port accepts determines the untagged VLAN membership to which the port is assigned during the session. If another authenticated client session begins later on the same port while an earlier session is active, the later session replaces the currently active session and will be on the untagged VLAN membership specified by the RADIUS server for the later session.

Example: Configuring Client-Based 802.1X Authentication

This example enables ports A10-A12 to operate as authenticators, and then configures the ports for client-based authentication.

```
ProCurve(config)# aaa port-access authenticator a10-A12
ProCurve(config)# aaa port-access authenticator a10-A12 client-limit 4
```

Figure 9-2. Example of Configuring Client-Based 802.1X Authentication
Configuring Port-Based and Client-Based Access Control (802.1X)
Configuring Switch Ports as 802.1X Authenticators

Example: Configuring Port-Based 802.1X Authentication
This example enables ports A13-A15 to operate as authenticators, and then configures the ports for port-based authentication.

```
ProCurve(config)# aaa port-access authenticator a13-a15
```

Figure 9-3. Example of Configuring Port-Based 802.1X Authentication

2. Reconfigure Settings for Port-Access
The commands in this section are initially set by default and can be reconfigured as needed.

Syntax: `aaa port-access authenticator < port-list >`  
[control < authorized | auto | unauthorized >]

Controls authentication mode on the specified port:

- **authorized**: Also termed “Force Authorized”. Gives access to a device connected to the port. In this case, the device does not have to provide 802.1X credentials or support 802.1X authentication. (You can still configure console, Telnet, or SSH security on the port.)
- **auto** (the default): The device connected to the port must support 802.1X authentication and provide valid credentials to get network access. (Optional: You can use the Open VLAN mode to provide a path for clients without 802.1X supplicant software to download this software and begin the authentication process. Refer to “802.1X Open VLAN Mode” on page 9-28.)
- **unauthorized**: Also termed “Force Unauthorized”. Do not grant access to the network, regardless of whether the device provides the correct credentials and has 802.1X support. In this state, the port blocks access to any connected device.
Configuring Port-Based and Client-Based Access Control (802.1X)
Configuring Switch Ports as 802.1X Authenticators

[quiet-period < 0 - 65535 >]
Sets the period during which the port does not try to acquire a supplicant. The period begins after the last attempt authorized by the max-requests parameter fails (next page). (Default: 60 seconds)

[tx-period < 0 - 65535 >]
Sets the period the port waits to retransmit the next EAPOL PDU during an authentication session. (Default: 30 seconds)

[supplicant-timeout < 1 - 300 >]
Sets the period of time the switch waits for a supplicant response to an EAP request. If the supplicant does not respond within the configured time frame, the session times out. (Default: 30 seconds)

[server-timeout < 1 - 300 >]
Sets the period of time the switch waits for a server response to an authentication request. If there is no response within the configured time frame, the switch assumes that the authentication attempt has timed out. Depending on the current max-requests setting, the switch will either send a new request to the server or end the authentication session. (Default: 30 seconds)

[max-requests < 1 - 10 >]
Sets the number of authentication attempts that must time-out before authentication fails and the authentication session ends. If you are using the Local authentication option, or are using RADIUS authentication with only one host server, the switch will not start another session until a client tries a new access attempt. If you are using RADIUS authentication with two or three host servers, the switch will open a session with each server, in turn, until authentication occurs or there are no more servers to try. During the quiet-period (previous page), if any, you cannot reconfigure this parameter. (Default: 2)

—Continued—
Configuring Port-Based and Client-Based Access Control (802.1X)
Configuring Switch Ports as 802.1X Authenticators

[reauth-period < 0 - 9999999 >]
Sets the period of time after which clients connected must be re-authenticated. When the timeout is set to 0 the reauthentication is disabled (Default: 0 second)

[unauth-vid < vlan-id >]
Configures an existing static VLAN to be the Unauthorized-Client VLAN. This enables you to provide a path for clients without supplicant software to download the software and begin an authentication session. Refer to “802.1X Open VLAN Mode” on page 9-28.

[logoff-period] < 1 - 999999999 >
Configures the period of time the switch waits for client activity before removing an inactive client from the port. (Default: 300 seconds)

[unauth-period < 0-255 >]
Specifies a delay in seconds for placing a port on the Unauthorized-Client VLAN. This delay allows more time for a client with 802.1X supplicant capability to initiate an authentication session. If a connected client does not initiate a session before the timer expires, the port is assigned to the Unauthenticated-Client VLAN. (Default: 0 seconds)

[auth-vid < vid >]
Configures an existing, static VLAN to be the Authorized-Client VLAN. Refer to “802.1X Open VLAN Mode” on page 9-28.
3. Configure the 802.1X Authentication Method

This task specifies how the switch authenticates the credentials provided by a supplicant connected to a switch port configured as an 802.1X authenticator.

**Syntax:**

```none
aaa authentication port-access < local | eap-radius | chap-radius >
```

Determines the type of RADIUS authentication to use.

- **local** Use the switch's local username and password for supplicant authentication.
- **eap-radius** Use EAP-RADIUS authentication. (Refer to the documentation for your RADIUS server application.)
- **chap-radius** Use CHAP-RADIUS (MD-5) authentication. (Refer to the documentation for your RADIUS server application.)

For example, to enable the switch to perform 802.1X authentication using one or more EAP-capable RADIUS servers:

```none
ProCurve(config)# aaa authentication port-access eap-radius
ProCurve(config)# show auth
```

**Figure 9-4. Example of 802.1X (Port-Access) Authentication**

802.1X (Port-Access) configured for EAP-RADIUS authentication.
4. Enter the RADIUS Host IP Address(es)

If you select either `eap-radius` or `chap-radius` for the authentication method, configure the switch to use 1, 2, or 3 RADIUS servers for authentication. The following syntax shows the basic commands. For coverage of all commands related to RADIUS server configuration, refer to chapter 5, “RADIUS Authentication and Accounting”.

**Syntax:**
```
radius host < ip-address >
```

*Adds a server to the RADIUS configuration.*

```
[key < server-specific key-string >]
```

*Optional. Specifies an encryption key for use during authentication (or accounting) sessions with the specified server. This key must match the key used on the RADIUS server. Use this option only if the specified server requires a different key than configured for the global encryption key.*

**Syntax:**
```
radius-server key < global key-string >
```

*Specifies the global encryption key the switch uses for sessions with servers for which the switch does not have a server-specific key. This key is optional if all RADIUS server addresses configured in the switch include a server-specific encryption key.*

5. Enable 802.1X Authentication on the Switch

After configuring 802.1X authentication as described in the preceding four sections, activate it with this command:

**Syntax:**
```
aaa port-access authenticator active
```

*Activates 802.1X port-access on ports you have configured as authenticators.*
6. Optionally Resetting Authenticator Operation

After authentication has begun operating, these commands can be used to reset authentication and related statistics on specific ports.

**Syntax:**   aaaa port-access authenticator < port-list >

- **initialize**
  
  On the specified ports, blocks inbound and outbound traffic and restarts the 802.1X authentication process. This happens only on ports configured with control auto and actively operating as 802.1X authenticators.

- **reauthenticate**
  
  On the specified ports, forces reauthentication (unless the authenticator is in “HELD” state).

- **clear-statistics**
  
  On the specified ports, clears authenticator statistics counters.

7. Optional: Configure 802.1X Controlled Directions

After you enable 802.1X authentication on specified ports, you can use the `aaa port-access controlled-directions` command to configure how a port transmits traffic before it successfully authenticates a client and enters the authenticated state.

As documented in the IEEE 802.1X standard, an 802.1X-aware port that is unauthenticated can control traffic in either of the following ways:

- In both ingress and egress directions by disabling both the reception of incoming frames and transmission of outgoing frames.
- Only in the ingress direction by disabling only the reception of incoming frames.
Prerequisite. As documented in the IEEE 802.1X standard, the disabling of incoming traffic and transmission of outgoing traffic on an 802.1X-aware egress port in an unauthenticated state (using the `aaa port-access controlled-directions` command) is supported only if:

- The port is configured as an edge port in the network using the `spanning-tree edge-port` command.
- The 802.1s Multiple Spanning Tree Protocol (MSTP) or 802.1w Rapid Spanning Tree Protocol (RSTP) is enabled on the switch. MSTP and RSTP improve resource utilization while maintaining a loop-free network.

For information on how to configure the prerequisites for using the `aaa port-access controlled-directions` command, see Chapter 4, “Multiple Instance Spanning-Tree Operation” in the `Advanced Traffic Management Guide`.

Syntax:  
`aaa port-access <port-list> controlled-directions <both | in>`

- **both** (default): Incoming and outgoing traffic is blocked on an 802.1X-aware port before authentication occurs.
- **in**: Incoming traffic is blocked on an 802.1X-aware port before authentication occurs. Outgoing traffic with unknown destination addresses is flooded on unauthenticated 802.1X-aware ports.

Wake-on-LAN Traffic

The Wake-on-LAN feature is used by network administrators to remotely power on a sleeping workstation (for example, during early morning hours to perform routine maintenance operations, such as patch management and software updates).

The `aaa port-access controlled-direction` command allows Wake-on-LAN traffic to be transmitted on an 802.1X-aware egress port that has not yet transitioned to the 802.1X authenticated state; the `controlled-direction both` setting prevents Wake-on-LAN traffic to be transmitted on an 802.1X-aware egress port until authentication occurs.

Note

Although the `controlled-direction in` setting allows Wake-on-LAN traffic to traverse the switch through unauthenticated 802.1X-aware egress ports, it does not guarantee that the Wake-on-LAN packets will arrive at their destination. For example, firewall rules on other network devices and VLAN rules may prevent these packets from traversing the network.
Configuring Port-Based and Client-Based Access Control (802.1X)
Configuring Switch Ports as 802.1X Authenticators

Operating Notes

- Using the `aaa port-access controlled-directions in` command, you can enable the transmission of Wake-on-LAN traffic on unauthenticated egress ports that are configured for any of the following port-based security features:
  - 802.1X authentication
  - MAC authentication
  - Web authentication

Because a port can be configured for more than one type of authentication to protect the switch from unauthorized access, the last setting you configure with the `aaa port-access controlled-directions` command is applied to all authentication methods configured on the switch.

For information about how to configure and use MAC and Web authentication, refer to chapter 3, “Web and MAC Authentication”.

- To display the currently configured 802.1X Controlled Directions value, enter the `show port-access authenticator config` command.

- When an 802.1X-authenticated port is configured with the `controlled-directions in` setting, eavesdrop prevention is not supported on the port.

Example: Configuring 802.1X Controlled Directions

The following example shows how to enable the transmission of Wake-on-LAN traffic in the egress direction on an 802.1X-aware port before it transitions to the 802.1X authenticated state and successfully authenticates a client device.

```
ProCurve(config)# aaa port-access authenticator a10
ProCurve(config)# aaa authentication port-access eap-radius
ProCurve(config)# aaa port-access authenticator active
ProCurve(config)# aaa port-access a10 controlled-directions in
```

Figure 9-5. Example of Configuring 802.1X Controlled Directions
802.1X Open VLAN Mode

Introduction

This section describes how to use the 802.1X Open VLAN mode to provide a path for clients that need to acquire 802.1X supplicant software before proceeding with the authentication process. The Open VLAN mode involves options for configuring unauthorized-client and authorized-client VLANs on ports configured as 802.1X authenticators.

Configuring the 802.1X Open VLAN mode on a port changes how the port responds when it detects a new client. In earlier releases, a “friendly” client computer not running 802.1X supplicant software could not be authenticated on a port protected by 802.1X access security. As a result, the port would become blocked and the client could not access the network. This prevented the client from:

- Acquiring IP addressing from a DHCP server
- Downloading the 802.1X supplicant software necessary for an authentication session

The 802.1X Open VLAN mode solves this problem by temporarily suspending the port’s static VLAN memberships and placing the port in a designated Unauthorized-Client VLAN (sometimes termed a guest VLAN). In this state the client can proceed with initialization services, such as acquiring IP addressing and 802.1X client software, and starting the authentication process.
On ports configured to allow multiple sessions using 802.1X client-based access control, all clients must use the same untagged VLAN. On a given port where there are no currently active, authenticated clients, the first authenticated client determines the untagged VLAN in which the port will operate for all subsequent, overlapping client sessions.

If the switch operates in an environment where some valid clients will not be running 802.1X supplicant software and need to download it from your network. Then, because such clients would need to use the Unauthorized-Client VLAN and authenticated clients would be using a different VLAN (for security reasons), allowing multiple clients on an 802.1X port can result in blocking some or all clients needing to use the Unauthorized-Client VLAN.

On ports configured for port-based 802.1X access control, if multiple clients try to authenticate on the same port, the most recently authenticated client determines the untagged VLAN membership for that port. Clients that connect without trying to authenticate will have access to the untagged VLAN membership that is currently assigned to the port.

**VLAN Membership Priorities**

Following client authentication, an 802.1X port resumes membership in any tagged VLANs for which it is already assigned in the switch configuration. The port also becomes an untagged member of one VLAN according to the following order of options:

a. **1st Priority:** The port joins a VLAN to which it has been assigned by a RADIUS server during client authentication.

b. **2nd Priority:** If RADIUS authentication does not include assigning the port to a VLAN, then the switch assigns the port to the VLAN entered in the port’s 802.1X configuration as an Authorized-Client VLAN, if configured.

c. **3rd Priority:** If the port does not have an Authorized-Client VLAN configured, but does have a static, untagged VLAN membership in its configuration, then the switch assigns the port to this VLAN.

A port assigned to a VLAN by an Authorized-Client VLAN configuration (or a RADIUS server) will be an untagged member of the VLAN for the duration of the authenticated session. This applies even if the port is also configured in the switch as a tagged member of the same VLAN.
After client authentication, the port resumes membership in any tagged VLANs for which it is configured. If the port is a tagged member of a VLAN used for 1 or 2 listed above, then it also operates as an untagged member of that VLAN while the client is connected. When the client disconnects, the port reverts to tagged membership in the VLAN.

Use Models for 802.1X Open VLAN Modes

You can apply the 802.1X Open VLAN mode in more than one way. Depending on your use, you will need to create one or two static VLANs on the switch for exclusive use by per-port 802.1X Open VLAN mode authentication:

- **Unauthorized-Client VLAN**: Configure this VLAN when unauthenticated, friendly clients will need access to some services before being authenticated or instead of being authenticated.

- **Authorized-Client VLAN**: Configure this VLAN for authenticated clients when the port is not statically configured as an untagged member of a VLAN you want clients to use, or when the port is statically configured as an untagged member of a VLAN you do not want clients to use. (A port can be configured as untagged on only one port-based VLAN. When an Authorized-Client VLAN is configured, it will always be untagged and will block the port from using a statically configured, untagged membership in another VLAN.) Note that after client authentication, the port returns to membership in any tagged VLANs for which it is configured. See the "Note", above.
Table 9-1. 802.1X Open VLAN Mode Options

<table>
<thead>
<tr>
<th>802.1X Per-Port Configuration</th>
<th>Port Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>No Open VLAN mode:</td>
<td>The port automatically blocks a client that cannot initiate an authentication session.</td>
</tr>
<tr>
<td>Open VLAN mode with both of the following configured:</td>
<td></td>
</tr>
</tbody>
</table>
| Unauthorized-Client VLAN      | - When the port detects a client without 802.1X supplicant capability, it automatically becomes an untagged member of this VLAN. If you previously configured the port as a static, tagged member of the VLAN, membership temporarily changes to untagged while the client remains unauthenticated.  
- If the port already has a statically configured, untagged membership in another VLAN, then the port temporarily closes access to this other VLAN while in the Unauthorized-Client VLAN.  
- To limit security risks, the network services and access available on the Unauthorized-Client VLAN should include only what a client needs to enable an authentication session. If the port is statically configured as a tagged member of any other VLANs, access to these VLANs is blocked while the port is a member of the Unauthorized-Client VLAN. |

Note for a Port Configured To Allow Multiple Client Sessions: If any previously authenticated clients are using a port assigned to a VLAN other than the Unauthorized-Client VLAN, then a later client that is not running 802.1X supplicant software is blocked on the port until all other, authenticated clients on the port have disconnected.
### 802.1X Per-Port Configuration

<table>
<thead>
<tr>
<th>Authorized-Client VLAN</th>
<th>Port Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>• After client authentication, the port drops membership in the Unauthorized-Client VLAN and becomes an untagged member of this VLAN.</td>
<td></td>
</tr>
</tbody>
</table>

**Notes:** If the client is running an 802.1X supplicant application when the authentication session begins, and is able to authenticate itself before the switch assigns the port to the Unauthorized-Client VLAN, then the port does not become a member of the Unauthorized-Client VLAN. On the switches covered in this guide, you can use the `unauth-period` command—page 9-22—to delay moving the port into the Unauthorized-Client VLAN.

If RADIUS authentication assigns a VLAN and there are no other authenticated clients on the port, then the port becomes a member of the RADIUS-assigned VLAN—instead of the Authorized-Client VLAN—while the client is connected.

• If the port is statically configured as a tagged member of a VLAN, and this VLAN is used as the Authorized-Client VLAN, then the port temporarily becomes an untagged member of this VLAN when the client becomes authenticated.

• If the port is statically configured as a tagged member of a VLAN, the port returns to tagged membership in this VLAN upon successful authentication. This happens even if the RADIUS server assigns the port to another, authorized VLAN. If the port is already configured as a tagged member of a VLAN that RADIUS assigns as an authorized VLAN, then the port becomes an untagged member of that VLAN for the duration of the client connection.
Open VLAN Mode with Only an Unauthorized-Client VLAN Configured:

- When the port detects a client, it automatically becomes an untagged member of this VLAN. To limit security risks, the network services and access available on this VLAN should include only what a client needs to enable an authentication session. If the port is statically configured as an untagged member of another VLAN, the switch temporarily removes the port from membership in this other VLAN while membership in the Unauthorized-Client VLAN exists.

- After the client is authenticated, and if the port is statically configured as an untagged member of another VLAN, the port’s access to this other VLAN is restored.

**Note:** If RADIUS authentication assigns the port to a VLAN, this assignment overrides any statically configured, untagged VLAN membership on the port (while the client is connected).

- If the port is statically configured as a tagged member of a VLAN, the port returns to tagged membership in this VLAN upon successful client authentication. This happens even if the RADIUS server assigns the port to another, authorized VLAN. Note that if the port is already configured as a tagged member of a VLAN that RADIUS assigns as an authorized VLAN, then the port becomes an untagged member of that VLAN for the duration of the client connection.

**Note for a Port Configured To Allow Multiple Client Sessions:** If any previously authenticated clients are using a port assigned to a VLAN other than the Unauthorized-Client VLAN (such as a RADIUS-assigned VLAN), then a later client that is not running 802.1X supplicant software is blocked on the port until all other, authenticated clients on the port have disconnected. Refer to figure 9-1 on page 9-12.
802.1X Open VLAN Mode

### 802.1X Per-Port Configuration

<table>
<thead>
<tr>
<th>802.1X Per-Port Configuration</th>
<th>Port Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open VLAN Mode with Only an Authorized-Client VLAN Configured:</td>
<td></td>
</tr>
<tr>
<td>• Port automatically blocks a client that cannot initiate an authentication session.</td>
<td></td>
</tr>
<tr>
<td>• If the client successfully completes an authentication session, the port becomes an untagged member of this VLAN.</td>
<td></td>
</tr>
<tr>
<td>• If the port is statically configured as a tagged member of any other VLAN, the port returns to tagged membership in this VLAN upon successful client authentication. This happens even if the RADIUS server assigns the port to another, authorized VLAN. If the port is already configured as a tagged member of a VLAN that RADIUS assigns as an authorized VLAN, then the port becomes an untagged member of that VLAN for the duration of the client connection.</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** An authorized-client VLAN configuration can be overridden by a RADIUS authentication that assigns a VLAN. (Refer to figure 9-1 on page 9-12.)
Operating Rules for Authorized-Client and Unauthorized-Client VLANs

<table>
<thead>
<tr>
<th>Condition</th>
<th>Rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>Static VLANs used as Authorized-Client or Unauthorized-Client VLANs</td>
<td>These must be configured on the switch before you configure an 802.1X authenticator port to use them. (Use the <code>vlan &lt;vlan-id&gt;</code> command or the VLAN Menu screen in the Menu interface.)</td>
</tr>
<tr>
<td>VLAN Assignment Received from a RADIUS Server</td>
<td>If the RADIUS server specifies a VLAN for an authenticated supplicant connected to an 802.1X authenticator port, this VLAN assignment overrides any Authorized-Client VLAN assignment configured on the authenticator port. This is because membership in both VLANs is untagged, and the switch allows only one untagged, port-based VLAN membership per-port. For example, suppose you configured port A4 to place authenticated supplicants in VLAN 20. If a RADIUS server authenticates supplicant “A” and assigns this supplicant to VLAN 50, then the port can access VLAN 50 as an untagged member while the client session is running. When the client disconnects from the port, then the port drops these assignments and uses the untagged VLAN memberships for which it is statically configured. (After client authentication, the port resumes any tagged VLAN memberships for which it is already configured. For details, refer to the Note on page 9-30.)</td>
</tr>
</tbody>
</table>
| Temporary VLAN Membership During a Client Session    | • Port membership in a VLAN assigned to operate as the Unauthorized-Client VLAN is temporary, and ends when the client receives authentication or the client disconnects from the port, whichever is first. In the case of the multiple clients allowed on switches covered in this guide, the first client to authenticate determines the untagged VLAN membership for the port until all clients have disconnected. Any other clients that cannot operate in that VLAN are blocked at that point.  
• Port membership in a VLAN assigned to operate as the Authorized-Client VLAN ends when the client disconnects from the port. If a VLAN assignment from a RADIUS server is used instead, the same rule applies. In the case of the multiple clients allowed on switches, the port maintains the same VLAN as long as there is any authenticated client using the VLAN. When the last client disconnects, then the port reverts to only the VLAN(s) for which it is statically configured as a member. |
### Configuring Port-Based and Client-Based Access Control (802.1X)

#### 802.1X Open VLAN Mode

<table>
<thead>
<tr>
<th>Condition</th>
<th>Rule</th>
</tr>
</thead>
</table>
| Effect of Unauthorized-Client VLAN session on untagged port VLAN membership | - When an unauthenticated client connects to a port that is already configured with a static, untagged VLAN, the switch temporarily moves the port to the Unauthorized-Client VLAN (also untagged). (While the Unauthorized-Client VLAN is in use, the port does not access any other VLANs.)  
  - If the client disconnects, the port leaves the Unauthorized-Client VLAN and re-acquires membership in all the statically configured VLANs to which it belongs.  
  - If the client becomes authenticated, the port leaves the Unauthorized-Client VLAN and joins the appropriate VLAN. (Refer to “VLAN Membership Priorities” on page 9-29.)  
  - In the case of the multiple clients allowed on switches, if an authenticated client is already using the port for a different VLAN, then any other unauthenticated clients needing to use the Unauthorized-Client VLAN are blocked. |
| Effect of Authorized-Client VLAN session on untagged port VLAN membership. | - When a client becomes authenticated on a port that is already configured with a static, untagged VLAN, the switch temporarily moves the port to the Authorized-Client VLAN (also untagged). While the Authorized-Client VLAN is in use, the port does not have access to the statically configured, untagged VLAN.  
  - When the authenticated client disconnects, the switch removes the port from the Authorized-Client VLAN and moves it back to the untagged membership in the statically configured VLAN. (After client authentication, the port resumes any tagged VLAN memberships for which it is already configured. For details, refer to the Note on page 9-30.) |

**Note:** This rule assumes:  
- No alternate VLAN has been assigned by a RADIUS server.  
- No other authenticated clients are already using the port.

### Multiple Authenticator Ports Using the Same Unauthorized-Client and Authorized-Client VLANs

You can use the same static VLAN as the Unauthorized-Client VLAN for all 802.1X authenticator ports configured on the switch. Similarly, you can use the same static VLAN as the Authorized-Client VLAN for all 802.1X authenticator ports configured on the switch.  

**Caution:** Do not use the same static VLAN for both the unauthorized-client VLAN and the authorized-client VLAN. Using one VLAN for both creates a security risk by defeating the isolation of unauthenticated clients.

### Effect of Failed Client Authentication Attempt

This rule assumes no other authenticated clients are already using the port on a different VLAN.  

When there is an Unauthorized-Client VLAN configured on an 802.1X authenticator port, an unauthorized client connected to the port has access only to the network resources belonging to the Unauthorized-Client VLAN. This access continues until the client disconnects from the port. (If there is no Unauthorized-Client VLAN configured on the authenticator port, the port simply blocks access for any unauthorized client.)

## Configuring Port-Based and Client-Based Access Control (802.1X)

### 802.1X Open VLAN Mode

<table>
<thead>
<tr>
<th>Condition</th>
<th>Rule</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong> Limitation on Using an Unauthorized-Client VLAN on an 802.1X Port Configured to Allow Multiple-Client Access</td>
<td>You can optionally enable switches to allow up to 8 clients per-port. The Unauthorized-Client VLAN feature can operate on an 802.1X-configured port regardless of how many clients the port is configured to support. However, all clients on the same port must operate through the same untagged VLAN membership. This means that any client accessing a given port must be able to authenticate and operate on the same VLAN as any other previously authenticated clients that are currently using the port. Thus, an Unauthorized-Client VLAN configured on a switch port that allows multiple 802.1X clients cannot be used if there is already an authenticated client using the port on another VLAN. Also, a client using the Unauthenticated-Client VLAN will be blocked when another client becomes authenticated on the port. For this reason, the best utilization of the Unauthorized-Client VLAN feature is in instances where only one client is allowed per-port. Otherwise, unauthenticated clients are subject to being blocked at any time by authenticated clients using a different VLAN. (Using the same VLAN for authenticated and unauthenticated clients can create a security risk and is not recommended.)</td>
</tr>
</tbody>
</table>

### Note

If you use the same VLAN as the Unauthorized-Client VLAN for all authenticator ports, unauthenticated clients on different ports can communicate with each other.

### Setting Up and Configuring 802.1X Open VLAN Mode

**Preparation.** This section assumes use of both the Unauthorized-Client and Authorized-Client VLANs. Refer to Table 9-1 on page 9-31 for other options.

Before you configure the 802.1X Open VLAN mode on a port:

- Statically configure an “Unauthorized-Client VLAN” in the switch. The only ports that should belong to this VLAN are ports offering services and access you want available to unauthenticated clients. (802.1X authenticator ports do not have to be members of this VLAN.)

### Caution

Do not allow any port memberships or network services on this VLAN that would pose a security risk if exposed to an unauthorized client.
Statically configure an Authorized-Client VLAN in the switch. The only ports that should belong to this VLAN are ports offering services and access you want available to authenticated clients. 802.1X authenticator ports do not have to be members of this VLAN.

Note that if an 802.1X authenticator port is an untagged member of another VLAN, the port’s access to that other VLAN will be temporarily removed while an authenticated client is connected to the port. For example, if:

1. Port A5 is an untagged member of VLAN 1 (the default VLAN).
2. You configure port A5 as an 802.1X authenticator port.
3. You configure port A5 to use an Authorized-Client VLAN.

Then, if a client connects to port A5 and is authenticated, port A5 becomes an untagged member of the Authorized-Client VLAN and is temporarily suspended from membership in the default VLAN.

If you expect friendly clients to connect without having 802.1X supplicant software running, provide a server on the Unauthorized-Client VLAN for downloading 802.1X supplicant software to the client, and a procedure by which the client initiates the download.

A client must either have a valid IP address configured before connecting to the switch, or download one through the Unauthorized-Client VLAN from a DHCP server. In the latter case, you will need to provide DHCP services on the Unauthorized-Client VLAN.

Ensure that the switch is connected to a RADIUS server configured to support authentication requests from clients using ports configured as 802.1X authenticators. (The RADIUS server should not be on the Unauthorized-Client VLAN.)

Note that as an alternative, you can configure the switch to use local password authentication instead of RADIUS authentication. However, this is less desirable because it means that all clients use the same passwords and have the same access privileges. Also, you must use 802.1X supplicant software that supports the use of local switch passwords.

**Caution**

Ensure that you do not introduce a security risk by allowing Unauthorized-Client VLAN access to network services or resources that could be compromised by an unauthorized client.
Configuring General 802.1X Operation: These steps enable 802.1X authentication, and must be done before configuring 802.1X VLAN operation.

1. Enable 802.1X authentication on the individual ports you want to serve as authenticators. (The switch automatically disables LACP on the ports on which you enable 802.1X.) On the ports you will use as authenticators with VLAN operation, ensure that the port-control parameter is set to auto (the default). (Refer to “1. Enable 802.1X Authentication on Selected Ports” on page 9-18.) This setting requires a client to support 802.1X authentication (with 802.1X supplicant operation) and to provide valid credentials to get network access.

Syntax:  
```
aaa port-access authenticator < port-list > control auto
```

Activates 802.1X port-access on ports you have configured as authenticators.

2. Configure the 802.1X authentication type. Options include:

Syntax:  
```
aaa authentication port-access < local | eap-radius | chap-radius >
```

Determines the type of RADIUS authentication to use.

- **local**: Use the switch’s local username and password for supplicant authentication (the default).
- **eap-radius**: Use EAP-RADIUS authentication. (Refer to the documentation for your RADIUS server.
- **chap-radius**: Use CHAP-RADIUS (MD5) authentication. (Refer to the documentation for your RADIUS server software.)
3. If you selected either eap-radius or chap-radius for step 2, use the radius host command to configure up to three RADIUS server IP address(es) on the switch.

   Syntax: radius host < ip-address >

   Adds a server to the RADIUS configuration.

   [key < server-specific key-string >]

   Optional. Specifies an encryption key for use with the specified server. This key must match the key used on the RADIUS server. Use this option only if the specified server requires a different key than configured for the global encryption key.

   Syntax: radius-server key < global key-string >

   Specifies the global encryption key the switch uses for sessions with servers for which the switch does not have a server-specific key. This key is optional if all RADIUS server addresses configured in the switch include a server-specific encryption key.

4. Activate authentication on the switch.

   Syntax: aaa port-access authenticator active

   Activates 802.1X port-access on ports you have configured as authenticators.

5. Test both the authorized and unauthorized access to your system to ensure that the 802.1X authentication works properly on the ports you have configured for port-access.

   Note

   If you want to implement the optional port-security feature on the switch, you should first ensure that the ports you have configured as 802.1X authenticators operate as expected. Then refer to “Option For Authenticator Ports: Configure Port-Security To Allow Only 802.1X-Authenticated Devices” on page 9-44.

After you complete steps 1 and 2, the configured ports are enabled for 802.1X authentication (without VLAN operation), and you are ready to configure VLAN Operation.
Configuring 802.1X Open VLAN Mode. Use these commands to actually configure Open VLAN mode. For a listing of the steps needed to prepare the switch for using Open VLAN mode, refer to “Preparation” on page 9-38.

Syntax:  
```
aaa port-access authenticator < port-list >  
[auth-vid < vlan-id >]
```

*Configures an existing, static VLAN to be the Authorized-Client VLAN.*

```
[< unauth-vid < vlan-id >]
```

*Configures an existing, static VLAN to be the Unauthorized-Client VLAN.*

For example, suppose you want to configure 802.1X port-access with Open VLAN mode on ports A10 - A20 and:

- These two static VLANs already exist on the switch:
  - Unauthorized, VID = 80
  - Authorized, VID = 81
- Your RADIUS server has an IP address of 10.28.127.101. The server uses `rad4all` as a server-specific key string. The server is connected to a port on the Default VLAN.
- The switch's default VLAN is already configured with an IP address of 10.28.127.100 and a network mask of 255.255.255.0

ProCurve(config)# aaa authentication port-access eap-radius

*Configures the switch for 802.1X authentication using an EAP-RADIUS server.*

ProCurve(config)# aaa port-access authenticator a10-a20

*Configures ports A10 - A20 as 802.1 authenticator ports.*

ProCurve(config)# radius host 10.28.127.101 key rad4all

*Configures the switch to look for a RADIUS server with an IP address of 10.28.127.101 and an encryption key of rad4all.*

ProCurve(config)# aaa port-access authenticator e a10-a20 unauth-vid 80

*Configures ports A10 - A20 to use VLAN 80 as the Unauthorized-Client VLAN.*

ProCurve(config)# aaa port-access authenticator e a10-a20 auth-vid 81

*Configures ports A10 - A20 to use VLAN 81 as the Authorized-Client VLAN.*

ProCurve(config)# aaa port-access authenticator active

*Activates 802.1X port-access on ports you have configured as authenticators.*
Inspecting 802.1X Open VLAN Mode Operation. For information and an example on viewing current Open VLAN mode operation, refer to “Viewing 802.1X Open VLAN Mode Status” on page 9-53.

802.1X Open VLAN Operating Notes

- Although you can configure Open VLAN mode to use the same VLAN for both the Unauthorized-Client VLAN and the Authorized-Client VLAN, this is not recommended. Using the same VLAN for both purposes allows unauthenticated clients access to a VLAN intended only for authenticated clients, which poses a security breach.

- While an Unauthorized-Client VLAN is in use on a port, the switch temporarily removes the port from any other statically configured VLAN for which that port is configured as a member. Note that the Menu interface will still display the port’s statically configured VLAN(s).

- A VLAN used as the Unauthorized-Client VLAN should not allow access to resources that must be protected from unauthenticated clients.

- If a port is configured as a tagged member of VLAN “X”, then the port returns to tagged membership in VLAN “X” upon successful client authentication. This happens even if the RADIUS server assigns the port to another, authorized VLAN “Y”. Note that if RADIUS assigns VLAN “X” as an authorized VLAN, then the port becomes an untagged member of VLAN “X” for the duration of the client connection. (If there is no Authorized-Client or RADIUS-assigned VLAN, then an authenticated client without tagged VLAN capability can access only a statically configured, untagged VLAN on that port.)

- When a client’s authentication attempt on an Unauthorized-Client VLAN fails, the port remains a member of the Unauthorized-Client VLAN until the client disconnects from the port.

- During an authentication session on a port in 802.1X Open VLAN mode, if RADIUS specifies membership in an untagged VLAN, this assignment overrides port membership in the Authorized-Client VLAN. If there is no Authorized-Client VLAN configured, then the RADIUS assignment overrides any untagged VLAN for which the port is statically configured.

- If the only authenticated client on a port loses authentication during a session in 802.1X Open VLAN mode, the port VLAN membership reverts back to the Unauthorized-Client VLAN. If there is no Unauthorized-Client VLAN configured, then the client loses access to the port until it can reauthenticate itself. If there are multiple clients authenticated on the port, if one client loses access and attempts to re-authenticate, that client will be handled as a new client on the port.
Option For Authenticator Ports: Configure Port-Security To Allow Only 802.1X-Authenticated Devices

If 802.1X authentication is disabled on a port or set to authorized (Force Authorize), the port can allow access to a non-authenticated client. Port-Security operates with 802.1X authentication only if the selected ports are configured as 802.1X with the control mode in the port-access authenticator command set to auto (the default setting). For example, if port A10 was at a non-default 802.1X setting and you wanted to configure it to support the port-security option, you would use the following `aaa port-access` command:

```
ProCurve(config)# aaa port-access authenticator a10 control auto
ProCurve(config)# show port-access authenticator a10 config
```

<table>
<thead>
<tr>
<th>Port</th>
<th>Re-auth Period</th>
<th>Access Control</th>
<th>Max Requests</th>
<th>Quiet Period</th>
<th>TX Timeout</th>
<th>Supplicant Timeout</th>
<th>Server Timeout</th>
</tr>
</thead>
<tbody>
<tr>
<td>A10</td>
<td>No</td>
<td>Auto</td>
<td>2</td>
<td>60</td>
<td>30</td>
<td>30</td>
<td>30</td>
</tr>
</tbody>
</table>

Note

If 802.1X port-access is configured on a given port, then port-security learn-mode for that port must be set to either continuous (the default) or port-access.

In addition to the above, to use port-security on an authenticator port (chapter 10), use the per-port client-limit option to control how many MAC addresses of 802.1X-authenticated devices the port is allowed to learn. (Using client-limit sets 802.1X to client-based operation on the specified ports.) When this limit is reached, no further devices can be authenticated until a currently authenticated device disconnects and the current delay period or logoff period has expired.
Configuring Port-Based and Client-Based Access Control (802.1X)

Configuring Switch Ports To Operate As Supplicants for 802.1X Connections to Other Switches

### Configure the port access type.

**Syntax:**

```plaintext
aaa port-access auth < port-list > client-limit < 1 - 8>
```

Configures client-based 802.1X authentication on the specified ports and sets the number of authenticated devices the port is allowed to learn. For more on this command, refer to “Configuring Switch Ports as 802.1X Authenticators” on page 9-17.

— Or —

```plaintext
no aaa port-access auth < port-list > client-limit
```

Configures port-based 802.1X authentication on the specified ports, which opens the port. (Refer to “802.1X Port-Based Access Control” on page 9-5.)

### Configuring Switch Ports To Operate As Supplicants for 802.1X Connections to Other Switches

802.1X Authentication Commands  page 9-17

802.1X Suppliant Commands

```plaintext
[no] aaa port-access < supplicant < [ethernet] < port-list >
```

[auth-timeout | held-period | start-period | max-start | initialize | identity | secret | clear-statistics]

page 9-47

802.1X-Related Show Commands  page 9-50

RADIUS server configuration  pages 9-24

A switch port can operate as a supplicant in a connection to a port on another 802.1X-aware switch to provide security on links between 802.1X-aware switches. (A port can operate as both an authenticator and a supplicant.)
Example

Suppose that you want to connect two switches, where:
- Switch “A” has port A1 configured for 802.1X supplicant operation.
- You want to connect port A1 on switch “A” to port B5 on switch “B”.

1. When port A1 on switch “A” is first connected to a port on switch “B”, or if the ports are already connected and either switch reboots, port A1 begins sending start packets to port B5 on switch “B”.
   - If, after the supplicant port sends the configured number of start packets, it does not receive a response, it assumes that switch “B” is not 802.1X-aware, and transitions to the authenticated state. If switch “B” is operating properly and is not 802.1X-aware, then the link should begin functioning normally, but without 802.1X security.
   - If, after sending one or more start request packets, port A1 receives a request packet from port B5, then switch “B” is operating as an 802.1X authenticator. The supplicant port then sends a response/ID packet. If switch “B” is configured for RADIUS authentication, it forwards this request to a RADIUS server. If switch “B” is configured for Local 802.1X authentication, the authenticator compares the switch “A” response to its local username and password.

2. The RADIUS server then responds with an MD5 access challenge that switch “B” forwards to port A1 on switch “A”.

3. Port A1 replies with an MD5 hash response based on its username and password or other unique credentials. Switch “B” forwards this response to the RADIUS server.
4. The RADIUS server then analyzes the response and sends either a “success” or “failure” packet back through switch “B” to port A1.
   - A “success” response unblocks port B5 to normal traffic from port A1.
   - A “failure” response continues the block on port B5 and causes port A1 to wait for the “held-time” period before trying again to achieve authentication through port B5.

Supplicant Port Configuration

**Enabling a Switch Port as a Supplicant.** You can configure a switch port as a supplicant for a point-to-point link to an 802.1X-aware port on another switch. *Configure the port as a supplicant before configuring any supplicant-related parameters.*

**Syntax:**  
```
[no] aaa port-access supplicant [ethernet] <port-list>
```

*Configures a port as a supplicant with either the default supplicant settings or any previously configured supplicant settings, whichever is most recent. The “no” form of the command disables supplicant operation on the specified ports.*

**Configuring a Supplicant Switch Port.** You must enable supplicant operation on a port before changing the supplicant configuration. This means you must execute the supplicant command once without any other parameters, then execute it again with a supplicant parameter you want to configure. If the intended authenticator port uses RADIUS authentication, then use the *identity* and *secret* options to configure the RADIUS-expected credentials on the supplicant port. If the intended authenticator port uses Local 802.1X authentication, then use the *identity* and *secret* options to configure the authenticator switch’s local username and password on the supplicant port.

**Syntax:**  
```
aaa port-access supplicant [ethernet] <port-list>
```

*To enable supplicant operation on the designated ports, execute this command without any other parameters. After doing this, you can use the command again with the following parameters to configure supplicant operation. (Use one instance of the command for each parameter you want to configure. The no form disables supplicant operation on the designated port(s).)*
Configuring Port-Based and Client-Based Access Control (802.1X)
Configuring Switch Ports To Operate As Supplicants for 802.1X Connections to Other Switches

[identity < username >]

Sets the username and password to pass to the authenticator port when a challenge-request packet is received from the authenticator port due to an authentication request. If the intended authenticator port is configured for RADIUS authentication, then < username > and < password > must be the username and password expected by the RADIUS server. If the intended authenticator port is configured for Local authentication, then < username > and < password > must be the username and password configured on the Authenticator switch. (Default: Null.)

[secret]

Enter secret: < password >
Repeat secret: < password >

Sets the secret password to be used by the port supplicant when an MD5 authentication request is received from an authenticator. The switch prompts you to enter the secret password after the command is invoked.

[auth-timeout < 1 - 300 >]

Sets the delay period the port waits to receive a challenge from the authenticator. If the request times out, the port sends another request, up to the number of attempts specified by the max-start parameter. (Default: 30 seconds).

[max-start < 1 - 10 >]

Defines the maximum number of times the supplicant port requests authentication. See step 1 on page 9-46 for a description of how the port reacts to the authenticator response. (Default: 3).

[held-period < 0 - 65535 >]

Sets the time period the supplicant port waits after an active 802.1X session fails before trying to re-acquire the authenticator port. (Default: 60 seconds)

[start-period < 1 - 300 >]

Sets the delay between Start packet retransmissions. That is, after a supplicant sends a start packet, it waits during the start-period for a response. If no response comes during the start-period, the supplicant sends a new start packet. The max-start setting (above) specifies how many start attempts are allowed in the session. (Default: 30 seconds)
[initialize]

On the specified ports, blocks inbound and outbound traffic and restarts the 802.1X authentication process. Affects only ports configured as 802.1X supplicants.

[clear-statistics]

Clears and restarts the 802.1X supplicant statistics counters.

Show Commands for Port-Access Authenticator

**Syntax:** show port-access authenticator [<port-list>]
[config | statistics | session-counters | vlan]

- Without [<port-list> [config | statistics | session-counters | vlan]], displays whether port-access authenticator is active (Yes or No) and the status of all ports configured for 802.1X authentication. Includes the port traffic priority (CoS) assigned to inbound traffic and the rate-limit settings, if any, specified by a RADIUS server for a current 802.1X authenticated client session. (Refer to “RADIUS-Administered CoS and Rate-Limiting” on page 5-4 in this guide.)
- With <port-list> only, same as above, but only for the specified port. Does not display data for a specified port that is not enabled as an authenticator.
- With [<port-list> [config | statistics | session-counters | vlan]], displays the [config | statistics | session-counters] data for the specified port(s). Does not display data for a specified port that is not enabled as an authenticator.
- With [config | statistics | session-counters | vlan] only, displays the [config | statistics | session-counters] data for all ports enabled as authenticators.

For more on the [config | statistics | session-counters | vlan] options refer to the next section of this table.
show port-access authenticator  

(config [ < port-list > ])

Shows:
- Whether port-access authenticator is active
- The 802.1X configuration of ports configured as 802.1X authenticators (For descriptions of these elements, refer to the syntax descriptions under “1. Enable 802.1X Authentication on Selected Ports” on page 9-18.

Without < port-list >, the command lists ports configured as 802.1X port-access authenticators. Does not display data for a port not enabled as an authenticator.

statistics [ < port-list > ]

Shows:
- Whether port-access authenticator is active
- The statistics of the ports configured as 802.1X authenticators, including the supplicant's MAC address, as determined by the content of the last EAPOL frame received on the port.

Does not display data for a specified port that is not enabled as an authenticator.

session-counters [ < port-list > ]

Shows whether port-access authenticator is active, and includes the session status on the specified ports configured as 802.1X authenticators

Also, for each port, the “User” column lists the user name the supplicant used in its response packet. (For the switch, this is the identity setting included in the supplicant command—page 9-47.) Does not display data for a specified port that is not an authenticator.

vlan [ < port-list > ]

Shows per-port:
- The Access Control setting (control command on page 9-20)
- Unauth-VLAN ID (if any)
- Auth-VLAN ID (if any)

Viewing 802.1X Open VLAN Mode Status

You can examine the switch’s current VLAN status by using the `show port-access authenticator vlan` and `show port-access authenticator < port-list >` commands as illustrated in figure 9-9. Table 9-1 describes the data that these two commands display. Figure 9-10 shows related VLAN data that can help you to see how the switch is using statically configured VLANs to support 802.1X operation.

```
ProCurve(config)# show port-access authenticator vlan
Port Access Authenticator VLAN Configuration
  Port-access authenticator activated [No] : Yes
  Access Control VLAN ID VLAN ID
  |-----|-----|-----|
  1   Auto 100  101
  2   Auto 100  101
  3   Auto 100  101

ProCurve(config)# show port-access authenticator 1-4
Port Access Authenticator Status
  Port Status Authenticator State Authenticator Backend State Current VLAN ID Current Port COS Limit Inbound
  |-----|-----|-----|-----|-----|-----|-----|
  1   Closed Connecting Idle No-override No-override
  2   Open Authorized Idle 101 No-override No-override
  3   Closed Connecting Idle 100 No-override No-override
  4   Closed Disconnected Idle No PVID, No-override No-override
```

Items 1 through 3 indicate that an authenticated client is connected to port 2:
1. `Open` in the Status column
2. `Authorized` in the Authenticator State column
3. The Auth VLAN ID (101) is also in the Current VLAN ID column. (This assumes that the port is not a statically configured member of VLAN 101.)
4. A “0” in the row for port 3 indicates there is no Authorized VLAN configured for port 3.
5. No “PVID” means there is currently no untagged VLAN membership on port 4.

Figure 9-9. Example Showing Ports Configured for Open VLAN Mode
Configuring Port-Based and Client-Based Access Control (802.1X)
Displaying 802.1X Configuration, Statistics, and Counters

Thus, in the output shown in figure 9-9:

- When the **Auth VLAN ID** is configured and matches the **Current VLAN ID**, an authenticated client is connected to the port. (This assumes the port is not a statically configured member of the VLAN you are using for Auth VLAN.)

- When the **Unauth VLAN ID** is configured and matches the **Current VLAN ID**, an unauthenticated client is connected to the port. (This assumes the port is not a statically configured member of the VLAN you are using for Unauth VLAN.)

Note that because a temporary Open VLAN port assignment to either an authorized or unauthorized VLAN is an untagged VLAN membership, these assignments temporarily replace any other untagged VLAN membership that is statically configured on the port. For example, if port 12 is statically configured as an untagged member of VLAN 1, but is configured to use VLAN 25 as an authorized VLAN, then the port’s membership in VLAN 1 will be temporarily suspended whenever an authenticated 802.1X client is attached to the port.

| Table 9-3. Output for Determining Open VLAN Mode Status (Figure 9-9, Upper) |
|---------------------------------|-----------------------------|
| **Status Indicator** | **Meaning** |
| **Access Control** | This state is controlled by the following port-access command syntax: |
|  | ProCurve(config)# aaa port-access authenticator <port-list> control <authorized | auto | unauthorized> |
|  | **Auto**: Configures the port to allow network access to any connected device that supports 802.1X authentication and provides valid 802.1X credentials. (This is the default authenticator setting.) |
|  | **Authorized**: Configures the port for “Force Authorized”, which allows access to any device connected to the port, regardless of whether it meets 802.1X criteria. (You can still configure console, Telnet, or SSH security on the port.) |
|  | **Unauthorized**: Configures the port for “Force Unauthorized”, which blocks access to any device connected to the port, regardless of whether the device meets 802.1X criteria. |
| **Unauthorized VLAN ID** | `<vlan-id>`: Lists the VID of the static VLAN configured as the unauthorized VLAN for the indicated port. |
|  | 0: No unauthorized VLAN has been configured for the indicated port. |
| **Authorized VLAN ID** | `<vlan-id>`: Lists the VID of the static VLAN configured as the authorized VLAN for the indicated port. |
|  | 0: No authorized VLAN has been configured for the indicated port. |
### Table 9-4. Output for Determining Open VLAN Mode Status (Figure 9-9, Lower)

<table>
<thead>
<tr>
<th>Status Indicator</th>
<th>Meaning</th>
</tr>
</thead>
</table>
| Status           | **Closed:** Either no client is connected or the connected client has not received authorization through 802.1X authentication.  
|                  | **Open:** An authorized 802.1X supplicant is connected to the port. |
| Current VLAN ID  | `<vlan-id>`: Lists the VID of the static, untagged VLAN to which the port currently belongs.  
|                  | **No PVID:** The port is not an untagged member of any VLAN. |
| Current Port CoS | Refer to the section describing RADIUS support for Identity-Driven Management—IDM—in chapter 5, “RADIUS Authentication and Accounting” in this guide. |
| % Curr. Rate Limit Inbound | |

**Syntax:**  
show vlan `<vlan-id>`

Displays the port status for the selected VLAN, including an indication of which port memberships have been temporarily overridden by Open VLAN mode.
ProCurve(config)# show vlan 1
Status and Counters - VLAN Information - Ports - VLAN 1
802.1Q VLAN ID : 1
Name : DEFAULT_VLAN
Status : Static

<table>
<thead>

Overridden Port VLAN configuration

<table>
<thead>
<tr>
<th>Port</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>B1</td>
<td>Untagged</td>
</tr>
<tr>
<td>B3</td>
<td>Untagged</td>
</tr>
</tbody>
</table>

Note that ports B1 and B3 are not in the upper listing, but are included under “Overridden Port VLAN configuration”. This shows that static, untagged VLAN memberships on ports B1 and B3 have been overridden by temporary assignment to the authorized or unauthorized VLAN. Using the `show port-access authenticator <port-list>` command shown in figure 9-9 provides details.

Figure 9-10. Example of Showing a VLAN with Ports Configured for Open VLAN Mode

9-56
Show Commands for Port-Access Supplicant

**Syntax:**

```
show port-access supplicant [< port-list>] [statistics]
show port-access supplicant [< port-list>]
```

*Shows the port-access supplicant configuration (excluding the secret parameter) for all ports or < port-list> ports configured on the switch as supplicants. The Supplicant State can include the following:

- **Connecting** - Starting authentication.
- **Authenticated** - Authentication completed (regardless of whether the attempt was successful).
- **Acquired** - The port received a request for identification from an authenticator.
- **Authenticating** - Authentication is in progress.
- **Held** - Authenticator sent notice of failure. The supplicant port is waiting for the authenticator's held-period (page 9-47).

For descriptions of the supplicant parameters, refer to “Configuring a Supplicant Switch Port” on page 9-47.

```
show port-access supplicant [< port-list>] statistics
```

*Shows the port-access statistics and source MAC address(es) for all ports or < port-list> ports configured on the switch as supplicants. See the “Note on Supplicant Statistics”, below.

**Note on Supplicant Statistics.** For each port configured as a supplicant, show port-access supplicant statistics < port-list> displays the source MAC address and statistics for transactions with the authenticator device most recently detected on the port. If the link between the supplicant port and the authenticator device fails, the supplicant port continues to show data received from the connection to the most recent authenticator device until one of the following occurs:

- The supplicant port detects a different authenticator device.
- You use the `aaa port-access supplicant < port-list> clear-statistics` command to clear the statistics for the supplicant port.
- The switch reboots.
Thus, if the supplicant’s link to the authenticator fails, the supplicant retains the transaction statistics it most recently received until one of the above events occurs. Also, if you move a link with an authenticator from one supplicant port to another without clearing the statistics data from the first port, the authenticator’s MAC address will appear in the supplicant statistics for both ports.

How RADIUS/802.1X Authentication Affects VLAN Operation

**Static VLAN Requirement.** RADIUS authentication for an 802.1X client on a given port can include a (static) VLAN requirement. (Refer to the documentation provided with your RADIUS application.) The static VLAN to which a RADIUS server assigns a client must already exist on the switch. If it does not exist or is a dynamic VLAN (created by GVRP), authentication fails. Also, for the session to proceed, the port must be an untagged member of the required VLAN. If it is not, the switch temporarily reassigns the port as described below.

**If the Port Used by the Client Is Not Configured as an Untagged Member of the Required Static VLAN:** When a client is authenticated on port “N”, if port “N” is not already configured as an untagged member of the static VLAN specified by the RADIUS server, then the switch temporarily assigns port “N” as an untagged member of the required VLAN (for the duration of the 802.1X session). At the same time, if port “N” is already configured as an untagged member of another VLAN, port “N” loses access to that other VLAN for the duration of the session. (This is because a port can be an untagged member of only one VLAN at a time.)
For example, suppose that a RADIUS-authenticated, 802.1X-aware client on port A2 requires access to VLAN 22, but VLAN 22 is configured for no access on port A2, and VLAN 33 is configured as untagged on port A2:

![Figure 9-11. Example of an Active VLAN Configuration](image)

In figure 9-11, if RADIUS authorizes an 802.1X client on port A2 with the requirement that the client use VLAN 22, then:

- VLAN 22 becomes available as Untagged on port A2 for the duration of the session.
- VLAN 33 becomes unavailable to port A2 for the duration of the session (because there can be only one untagged VLAN on any port).

You can use the `show vlan <vlan-id>` command to view this temporary change to the active configuration, as shown below:

- You can see the temporary VLAN assignment by using the `show vlan <vlan-id>` command with the `<vlan-id>` of the static VLAN that the authenticated client is using.
Configuring Port-Based and Client-Based Access Control (802.1X)

How RADIUS/802.1X Authentication Affects VLAN Operation

With the preceding in mind, since (static) VLAN 33 is configured as untagged on port A2 (see figure 9-11), and since a port can be untagged on only one VLAN, port A2 loses access to VLAN 33 for the duration of the 802.1X session involving VLAN 22. You can verify the temporary loss of access to VLAN 33 with the `show vlan 33` command.

Even though port A2 is configured as Untagged on (static) VLAN 33 (see figure 9-11), it does not appear in the VLAN 33 listing while the 802.1X session is using VLAN 22 in the Untagged status. However, after the 802.1X session with VLAN 22 ends, the active configuration returns port A2 to VLAN 33.

This entry shows that port A2 is temporarily untagged on VLAN 22 for an 802.1X session. This is to accommodate an 802.1X client's access, authenticated by a RADIUS server, where the server included an instruction to put the client's access on VLAN 22.

Note: With the current VLAN configuration (figure 9-11), the only time port A2 appears in this `show vlan 22` listing is during an 802.1X session with an attached client. Otherwise, port A2 is not listed.
When the 802.1X client’s session on port A2 ends, the port discards the temporary untagged VLAN membership. At this time the static VLAN actually configured as untagged on the port again becomes available. Thus, when the RADIUS-authenticated 802.1X session on port A2 ends, VLAN 22 access on port A2 also ends, and the untagged VLAN 33 access on port A2 is restored.

![Image](image.png)

**Figure 9-14. The Active Configuration for VLAN 33 Restores Port A2 After the 802.1X Session Ends**

---

**Notes**

Any port VLAN-ID changes you make on 802.1X-aware ports during an 802.1X-authenticated session do not take effect until the session ends.

With GVRP enabled, a temporary, untagged static VLAN assignment created on a port by 802.1X authentication is advertised as an existing VLAN. If this temporary VLAN assignment causes the switch to disable a configured (untagged) static VLAN assignment on the port, then the disabled VLAN assignment is not advertised. When the 802.1X session ends, the switch:

- Eliminates and ceases to advertise the temporary VLAN assignment.
- Re-activates and resumes advertising the temporarily disabled VLAN assignment.
Operating Notes

- Applying Web Authentication or MAC Authentication Concurrently with Port-Based 802.1X Authentication: While 802.1X port-based access control can operate concurrently with Web Authentication or MAC Authentication, port-based access control is subordinate to Web-Auth and MAC-Auth operation. If 802.1X operates in port-based mode and MAC or Web authentication is enabled on the same port, any 802.1X authentication has no effect on the ability of a client to access the controlled port. That is, the client’s access will be denied until the client authenticates through Web-Auth or MAC-Auth on the port. Note also that a client authenticating with port-based 802.1X does not open the port in the same way that it would if Web-Auth or MAC-Auth were not enabled. That is, any non-authenticating client attempting to access the port after another client authenticates with port-based 802.1X would still have to authenticate through Web-Auth or MAC-Auth.
